We investigate the constraints on the scalar, vector and spin-3/2 dark matter interaction with the standard model particles, from the observations of dark matter relic density, the direct detection experiments of CDMS and XENON, and the indirect detection of the $\bar{p}/p$ ratio by PAMELA. A model independent way is adopted by constructing general 4-particle operators up to dimension 6 for the effective interaction between dark matter and standard model particles. We find that the constraints from different experiments are complementary with each other. Comparison among these constraints may exclude some effective models of dark matter and limit some parameters of others. The spin-independent direct detection gives strong constraints for some operators, while the indirect detection of $\bar{p}/p$ data can be more sensitive than direct detection or relic density for light dark matter (whose mass $\lesssim 70$ GeV) in some cases. The constraints on some operators for spin-3/2 dark matter are shown to be similar to those on their analogous operators for Dirac fermionic dark matter. There are still some operators not sensitive to the current dark matter direct and indirect search experiments.

I. INTRODUCTION

It is by now established [1–3] that about 23% of the constituents of the Universe are composed of dark matter (DM) [4–8]. However, its nature remains unclear. A well-motivated candidate for DM is the weakly interacting massive particle (WIMP), which must be stable, nonrelativistic, electrically neutral and colorless. If the WIMP mass is from a few GeV to TeV while their interaction strength is of the weak scale, they can naturally yield the observed relic density of DM [8]. Although there is no stable WIMP in the Standard Model (SM), WIMP candidates exist in various theoretical models trying to solve the SM problems at the weak scale, such as supersymmetric models [5, 9–13], extra dimensional models [14–21], little Higgs models [22–26], left-right symmetric models [27–30], and some other models (e.g. [31–34]).

The specific models mentioned above are very attractive, but still lack experimental support. The well-running LHC experiment may find some important signals of these models in the near future. However, if other new particle species are all so heavy that the DM particle is the only new particle within the reach of LHC, it will be very difficult to know which model the DM particle belongs to. In addition, it is possible that the DM particle may be first observed by direct or indirect detection experiments. These early observations may only provide information about some general properties of the DM particle, and may not be able to distinguish the underlying theories. Therefore, the model-independent studies of the DM phenomenology can play an important role as they may avoid theoretical bias [35–40]. Recently there have been quite a few papers to study various phenomenologies related with DM in the model-independent way [41–58]. Especially the relic density measured by WMAP [3], direct detection from CDMS [59, 60] and XENON [61, 62], and possible collider signals from Tevatron (e.g. [63, 64]) and from LHC (e.g. [65, 66]) are considered in these studies.

In our previous work [50], we investigated a general set of 4-fermion operators for the effective interaction between the spin-1/2 fermionic DM and the SM particles, and gave the phenomenological constraints from the observed DM relic density, the direct detection experiments by CDMS and XENON, and the indirect detection of the $\bar{p}/p$ ratio by PAMELA [67]. It was found that the constraints from different observations are quite complementary. Besides the possibility of spin-1/2 WIMPs, it is also possible that DM is composed of scalar, vector, or spin-3/2 WIMPs, which belong to different representations of Lorentz group. In these cases, the forms of possible effective operators are different. These differences may lead to distinguishable phenomenological results. In this work we extend our previous

analysis to the cases of scalar, vector and spin-3/2 DM. We will consider a general set of 4-particle operators up to dimension 6 for the effective interaction between the WIMPs and the SM fermions and compute their phenomenological constraints. We will use the updated limit of XENON100 SI direct detection [61], which is stronger than that adopted in our previous work [50].

This paper is organized as follows. In Sections II and III, the effective models of scalar and vector DM are discussed, respectively. In the subsections of these two sections, we explore the constraints on these models from the DM relic density, direct and indirect detection searches and the validity of effective theory, and then present the combined constraints on the effective coupling constants of these models. In Section IV, the study on the effective models of spin-3/2 DM are carried out briefly. The conclusions are given in Section V.

II. SCALAR DARK MATTER

Let us begin with the case that DM consists of complex scalar WIMPs (ϕ and its antiparticle $\phi^\dagger$). We will add remarks when there is a notable difference between this case and the case of real scalar WIMPs. In order to study phenomenologies in a model-independent way, we construct effective interaction operators between the WIMPs and the SM particles. These interaction operators are limited only by the requirements of Hermiticity, Lorentz invariance and CPT invariance.

We make the following assumptions similar to those in Ref. [38, 50]: (1) The WIMP is the only new particle species at the electroweak scale, and any other new particle species is much heavier than the WIMP. This implies that the thermal relic density of the WIMP is not affected by resonances or coannihilations. Thus it is possible to describe the interaction between the WIMPs and the SM particles in terms of an effective field theory. (2) The WIMP only interacts with the SM fermions through a 4-particle effective interaction of $\phi^\dagger$ - ϕ - $\bar{f}$ - f type, but not with gauge or Higgs bosons. For simplicity, this interaction is assumed to be dominated by only one form in the set of 4-particle operators. (3) The WIMP-antiWIMP annihilation channels to the SM fermion-antifermion pairs dominate over other possible channels. In other words, the possible channels to final states that include gauge or Higgs bosons are assumed to be negligible.

The effective interaction term of Lagrangian between two complex scalar WIMPs (ϕ and $\phi^\dagger$) and two SM fermions (f and $\bar{f}$) is given by only one of the following expressions:

$$\text{Scalar int. (S) : } \quad \mathcal{L}_S = \sum_f \frac{F_{S,f}}{\sqrt{2}} \phi^\dagger \phi \bar{f} f, \quad (1)$$

$$\text{Vector int. (V) : } \quad \mathcal{L}_V = \sum_f \frac{F_{V,f}}{\sqrt{2}} (\phi^\dagger i \overleftrightarrow{\partial}_\mu \phi) \bar{f} \gamma^\mu f, \quad (2)$$

$$\text{Scalar-pseudoscalar int. (SP) : } \quad \mathcal{L}_{SP} = \sum_f \frac{F_{SP,f}}{\sqrt{2}} \phi^\dagger \phi \bar{f} i \gamma_5 f, \quad (3)$$

$$\text{Vector-axialvector int. (VA) : } \quad \mathcal{L}_{VA} = \sum_f \frac{F_{VA,f}}{\sqrt{2}} (\phi^\dagger i \overleftrightarrow{\partial}_\mu \phi) \bar{f} \gamma^\mu \gamma_5 f, \quad (4)$$

where the sum of f is over all the SM fermions, the symbol $\overleftrightarrow{\partial}_\mu$ is short for $\overrightarrow{\partial}_\mu - \overleftarrow{\partial}_\mu$, that is, $\phi^\dagger \overleftrightarrow{\partial}_\mu \phi \equiv \phi^\dagger (\partial_\mu \phi) - (\partial_\mu \phi^\dagger) \phi$, and the effective coupling constants F_f are real-valued numbers. F_f have mass dimension of -1 for the dimension-5 operators (S and SP), and that of -2 for the dimension-6 operators (V and VA). We do not consider operators with more derivatives on the fields since these operators have higher mass dimensions such that they are more suppressed at low energy scale. Note that for the case of a real scalar WIMP, the WIMP vector current $\phi \overleftrightarrow{\partial}_\mu \phi$ vanishes so that the V and VA effective operators vanish, leaving only the S and SP interactions. Since F_f are real-valued, the transformation properties of the 4-particle operators, $\mathcal{L}_S$, $\mathcal{L}_V$, $\mathcal{L}_{SP}$ and $\mathcal{L}_{VA}$ under C, P and T are the same as the corresponding 4-fermion operators of Ref. [50]. All the operators are CPT invariant.

Each form of the interaction operators listed above describes an effective model in which the WIMPs couple to the SM fermions. For each case, we will calculate the corresponding annihilation and scattering cross sections, which depend on the WIMP mass M_ϕ and the coupling constants F_f . Associated with the recent experimental results of the DM relic density, direct and indirect detection experiments, the phenomenological constraints on F_f can be derived, respectively. Since the sensitive regions of different kinds of experiments vary in different effective models, it would be interesting and meaningful to compare these constraints.

FIG. 1. The predicted coupling constants F_f as functions of the scalar WIMP mass M_ϕ , fixed by the observed relic density, $\Omega_{\text{DM}} h^2 = 0.1109 \pm 0.0056$ [3], in each effective model. Frames in the left (right) column are results given for the case of universal couplings ($F_f \propto m_f$).

A. Scalar WIMP annihilation and relic density

In order to determine the relic density of WIMPs and the source function of cosmic-ray particles derived from WIMP annihilation in the Galactic halo, which is relevant to the DM indirect detection, we need to calculate the cross sections of WIMP-antiWIMP annihilation to fermion-antifermion pairs. For each case listed above, the result is given by

$$\sigma_{\text{S, ann}} = \frac{1}{8\pi} \sum_f \left(\frac{F_{\text{S},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_\phi^2}} \frac{(s - 4m_f^2)}{s}, \quad (5)$$

$$\sigma_{\text{V, ann}} = \frac{1}{12\pi} \sum_f \left(\frac{F_{\text{V},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_\phi^2}} \frac{(s - 4M_\phi^2)(s + 2m_f^2)}{s}, \quad (6)$$

$$\sigma_{\text{SP, ann}} = \frac{1}{8\pi} \sum_f \left(\frac{F_{\text{SP},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_\phi^2}}, \quad (7)$$

$$\sigma_{\text{VA, ann}} = \frac{1}{12\pi} \sum_f \left(\frac{F_{\text{VA},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_\phi^2}} \frac{(s - 4M_\phi^2)(s - 4m_f^2)}{s}, \quad (8)$$

where s is the square of the center-of-mass energy, M_ϕ is the WIMP mass, and c_f are the color factors, equal to 3 for quarks and 1 for leptons. For the case of real scalar WIMPs, due to the identity of WIMP and antiWIMP, the S and SP annihilation cross sections should include an additional factor of 4 if the Lagrangians are taken to be Eqs. (1) and (3) with $\phi^\dagger = \phi$. Eqs. (5) – (8) are also obtained in Ref. [38]. Taking the energy distributions of the initial particles into account, we need to calculate $\langle \sigma_{\text{ann}} v \rangle$, the thermal average of cross section multiplied by relative velocity (or

FIG. 2. The predicted thermal relic density (dashed lines) of complex scalar WIMPs with S, V, SP and VA interactions respectively. In the left (right) column, results are given for the case of universal couplings ($F_f \propto m_f$). The narrow horizontal solid band shows the range of the observed DM relic density, $\Omega_{DM} h^2 = 0.1109 \pm 0.0056$ [3].

Møller velocity, more exactly [68]).

In our previous work [50], following Ref. [68] we calculated $\langle\sigma_{\text{ann}}v\rangle$ in the “lab” frame (in which one of the two initial particles is at rest), because it can be proved that the calculation in this frame is equivalent to that obtained in the practical reference frame and more convenient. Thus we can expand s in the lab frame to be $s \simeq 4M_\phi^2 + M_\phi^2 v^2 + \frac{3}{4}M_\phi^2 v^4 + \mathcal{O}(v^6)$, and substitute it into Eqs. (5) – (8). Then we have the form $\sigma_{\text{ann}}v \simeq a_0 + a_1 v^2 + \mathcal{O}(v^4)$, which leads to $\langle\sigma_{\text{ann}}v\rangle \simeq a_0 + 6a_1 x^{-1} + \mathcal{O}(x^{-2})$ where $x \equiv M_\phi/T$ and T is the temperature of DM. On the other hand, we can also directly calculate $\langle\sigma_{\text{ann}}v\rangle$ in the practical reference frame following the method described in Ref. [69]. These two methods lead to the same results, i.e.,

$$\langle\sigma_{\text{S, ann}}v\rangle \simeq \frac{1}{4\pi} \sum_f \left(\frac{F_{\text{S},f}}{\sqrt{2}}\right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\phi^2}} \left[\left(1 - \frac{m_f^2}{M_\phi^2}\right) + \frac{3}{4} \left(-2 + 5\frac{m_f^2}{M_\phi^2}\right) \frac{T}{M_\phi} \right], \quad (9)$$

$$\langle\sigma_{\text{V, ann}}v\rangle \simeq \frac{1}{2\pi} \sum_f \left(\frac{F_{\text{V},f}}{\sqrt{2}}\right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\phi^2}} M_\phi^2 \left(2 + \frac{m_f^2}{M_\phi^2}\right) \frac{T}{M_\phi}, \quad (10)$$

$$\langle\sigma_{\text{SP, ann}}v\rangle \simeq \frac{1}{4\pi} \sum_f \left(\frac{F_{\text{SP},f}}{\sqrt{2}}\right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\phi^2}} \left[1 + \frac{-6 + 9m_f^2/M_\phi^2}{4(1 - m_f^2/M_\phi^2)} \frac{T}{M_\phi}\right], \quad (11)$$

$$\langle\sigma_{\text{VA, ann}}v\rangle \simeq \frac{1}{\pi} \sum_f \left(\frac{F_{\text{VA},f}}{\sqrt{2}}\right)^2 c_f \left(1 - \frac{m_f^2}{M_\phi^2}\right)^{3/2} M_\phi^2 \frac{T}{M_\phi}. \quad (12)$$

Note that the above results disagree with those in Ref. [38].

The evolution of the DM abundance is described by the Boltzmann equation

$$\frac{dn_\phi}{dt} + 3Hn_\phi = -\langle\sigma_{\text{ann}}v\rangle [n_\phi n_{\phi^\dagger} - n_\phi^{\text{eq}} n_{\phi^\dagger}^{\text{eq}}] = -\langle\sigma_{\text{ann}}v\rangle [(n_\phi)^2 - (n_\phi^{\text{eq}})^2], \quad (13)$$

where $H \equiv \dot{a}/a = \sqrt{8\pi\rho/(3M_{\text{Pl}}^2)}$ is the Hubble rate with M_{Pl} denoting the Planck mass, n_ϕ ($n_{\phi^\dagger}$) is the number density of WIMPs (antiWIMPs), and n_ϕ^{eq} ($n_{\phi^\dagger}^{\text{eq}}$) is the corresponding equilibrium number density. For complex scalar WIMPs without particle-antiparticle asymmetry, we have $n_\phi = n_{\phi^\dagger}$. Thus the total DM particle number density is $n_{\text{DM}} = 2n_\phi$ [5, 68]. Using the standard procedure [4, 5] to approximately solve the Boltzmann equation (13), we obtain a relic density of DM particles as

$$\Omega_{\text{DM}} h^2 = 2\Omega_\phi h^2 \simeq 2.08 \times 10^9 \text{ GeV}^{-1} \left(\frac{T_0}{2.725 \text{ K}}\right)^3 \frac{x_f}{M_{\text{Pl}} \sqrt{g_*(T_f)} (a_0 + 3a_1 x_f^{-1})}, \quad (14)$$

where $x_f \equiv M_\phi/T_f$ with T_f being the freeze-out temperature, $g_*(T_f)$ is effectively relativistic degrees of freedom at freeze-out, $T_0 = 2.725 \pm 0.002 \text{ K}$ [70] is the present CMB temperature, and a_0 and a_1 are coefficients in the expansion $\sigma_{\text{ann}}v \simeq a_0 + a_1 v^2 + \mathcal{O}(v^4)$. The freeze-out temperature parameter x_f is evaluated numerically by solving the equation

$$x_f = \ln \left[c(c+2) \sqrt{\frac{45}{8}} \frac{g M_\phi M_{\text{Pl}} (a_0 + 6a_1 x_f^{-1})}{2\pi^3 \sqrt{g_*(x_f)} x_f^{1/2}} \right], \quad (15)$$

where the order one parameter c is taken to be $1/2$ as usual. A notable difference between this calculation and our previous work [50] is that the degree of freedom of a scalar WIMP or antiWIMP is $g = 1$, while that of a fermionic WIMP is $g = 2$. The numerical result of $g_*(T)$ is taken from Ref. [71]. For the case of real scalar WIMPs, $n_{\text{DM}} = n_\phi$, and $n_{\phi^\dagger}$ in Eq. (13) should be replaced by n_ϕ so that the relic density will be one half of that for the complex scalar case given the same annihilation cross section.

The 7-year observation of WMAP [3] gives the DM relic density $\Omega_{\text{DM}} h^2 = 0.1109 \pm 0.0056$. With this result we estimate the relation between the effective coupling constants F_f and the WIMP mass M_ϕ in each effective model, as shown in Fig. 1. Two kinds of F_f are considered here. In the left column of Fig. 1, we show the results for the case when the effective couplings F_f to all the SM fermions are equal (universal couplings). In the right column of Fig. 1, we show the results for the case of $F_f \propto m_f$. This kind of proportionality may come from Yukawa couplings of a Higgs mediated interaction or some other unknown underlying mechanisms. In both cases, F_f decreases as M_ϕ increases for fixed $\Omega_{\text{DM}} h^2$ in each effective model. Besides, there are several interesting features in Fig. 1:

- In the case of $F_f \propto m_f$, the curves of F_f vs. M_ϕ have obvious downward bends at about $M_\phi \sim m_t = 171 \text{ GeV}$. The reason is that when $M_\phi > m_t$, the annihilation channel $\phi\phi^\dagger \rightarrow t\bar{t}$ is opened. Therefore because the couplings

are proportional to m_f , this channel gives a tremendous contribution to the total $\langle\sigma_{\text{ann}}v\rangle$ due to the huge mass gaps between t quark and other SM fermions.

- In the case of universal couplings, there are 2 pairs of nearly identical curves, that is, $S \simeq SP$ and $V \simeq VA$ if we denote this approximate identity of the two curves by a notation “ $\simeq$ ” for short here and henceforth. From Eq. (9) – (12) we can see that in each pair their corresponding $\langle\sigma_{\text{ann}}v\rangle$ differ only by terms of $\mathcal{O}(T/M_\phi)$ and/or terms of m_f^2/M_ϕ^2 . These differences are not important when we calculate the cold relic density.
- In the case of $F_f \propto m_f$, $S \simeq SP$ and $V \simeq VA$ are still almost true except that in some small regions the deviations of the two nearly identical curves in each pair become larger.

In Fig. 2 the curves of $\Omega_{\text{DM}}h^2$ vs. M_ϕ for fixed coupling constants in the complex scalar WIMP models of S, V, SP and VA interaction operators are shown. In the left (right) column, results are given for the case of universal couplings ($F_f \propto m_f$). The values of the couplings corresponding to the curves are denoted in each frames. All the curves in Fig. 2 bend more or less at about $M_\phi \sim 1.3, 4.2$ and 171 GeV corresponding to the masses of c, b and t quarks respectively, due to the opens of these heavy quark annihilation channels. An important qualitative difference between the curves of effective operators with different mass dimension in both Figs. 1 and 2 is that the curves for dimension-6 operators (V and VA) slope downward, while those for dimension-5 operators (S and SP) remain horizontal in most mass range. The reason has been showed explicitly in Eqs. (9) – (12). The annihilation cross section for dimension-6 operators have additional factors of M_ϕ^2 which suppress the relic density of large WIMP mass.

It is worth noting that the results in Figs. 1 and 2 are based on the assumptions presented at the beginning of this section. Otherwise if resonances, coannihilations or annihilations to final states other than fermion-antifermion pairs are significant, the actual curves in Figs. 1 and 2 will be much lower than those shown there, as pointed out in Ref. [38].

FIG. 3. The spin-independent (SI) WIMP-proton cross sections (dashed lines) for complex scalar WIMPs with S and V interactions. In the left (right) column, results are given for the case of universal couplings ($F_f \propto m_f$). The upper bounds set by CDMS II [59] and XENON100 [61] are also given in the frames for comparison.

B. Direct detection

In this subsection we discuss the direct detection constraints on the effective scalar WIMP models described by Eqs. (1) – (4). Direct detection experiments measure the recoil energy of the atomic nuclei when the WIMPs elastically scatter off them. Because of the complex structure of nucleons we have to study the WIMP-nucleon interactions with another set of effective interactions in terms of the nucleon fields, by substituting the quark field operators in Eqs. (1) – (4) with the nucleon field operators N ($N = p, n$) and associating the coupling constants of these two sets of effective interactions by the form factors of nucleons.

The velocity of the WIMP near the Earth is considered to be of the same order as the orbital velocity of the Sun, $v \simeq 0.001c$, and we can safely calculate the scattering cross sections in the low velocity limit. In this limit, only the time component of $\phi^\dagger i \overleftrightarrow{\partial}_\mu \phi$ and the spacial components of $\bar{N} \gamma^\mu \gamma_5 N$ survive, thus the VA interaction leads to an elastically scattering cross section with velocity suppression. On the other hand, $\bar{N} \gamma_5 N$ vanishes in this limit so that the SP interaction is not constrained by direct detection either. Therefore there is no measurable spin-dependent (SD) WIMP-nucleon scattering. This situation can be also understood by realizing that scalar WIMPs have no spin structure. The scattering cross sections induced by the remaining S and V interactions are both spin-independent (SI).

The calculation of scattering cross sections is much similar to our previous calculation for fermionic DM [50], so we will just outline the result. To compare with the result of CDMS [59] and XENON [61], the WIMP-nucleon cross sections are given as follows:

$$\text{Scalar int. : } \sigma_{S,\phi N} = \frac{m_N^2}{4\pi(M_\phi + m_N)^2} \left(\frac{F_{S,N}}{\sqrt{2}} \right)^2, \quad (16)$$

$$\text{Vector int. : } \sigma_{V,\phi N} = \frac{m_N^2 M_\phi^2}{\pi(M_\phi + m_N)^2} \left(\frac{F_{V,N}}{\sqrt{2}} \right)^2, \quad (17)$$

where F_N are the induced coupling constants of effective WIMP-nucleon interactions. F_N are related to the couplings to quarks F_q by form factors. For scalar interaction,

$$F_{S,N} = \sum_{q=u,d,s} F_{S,q} f_q^N \frac{m_N}{m_q} + \sum_{q=c,b,t} F_{S,q} f_q^N \frac{m_N}{m_q}, \quad (18)$$

where the nucleon form factors are $f_u^p = 0.020 \pm 0.004$, $f_d^p = 0.026 \pm 0.005$, $f_s^p = 0.118 \pm 0.062$, $f_u^n = 0.014 \pm 0.003$, $f_d^n = 0.036 \pm 0.008$, $f_s^n = 0.118 \pm 0.062$ [72, 73], and $f_Q^N = \frac{2}{27}(1 - f_u^N - f_d^N - f_s^N)$ for heavy quarks. For vector interaction,

$$F_{V,p} = 2F_{V,u} + F_{V,d}, \quad F_{V,n} = F_{V,u} + 2F_{V,d}, \quad (19)$$

which reflect the valence quark numbers in the nucleons. For the case of real scalar WIMPs, the vector interaction vanishes, and the scattering cross section of scalar interaction should include an additional factor 4 comparing to the case of complex scalar WIMPs.

In Fig. 3, we show the predicted elastic scattering cross sections between complex scalar WIMP and nucleon by different kinds of effective interactions. Then given the experimental bounds set by CDMS II [59] and XENON 100 [61], we can derive the upper bounds of coupling constants for different WIMP masses. The SP and VA interactions are not constrained by direct detection experiments, as stated above. Additionally, due to a difference of factor M_ϕ^2 in Eqs. (16) and (17), the predicted scattering cross section curves slope downward for scalar interactions, while they are nearly horizontal for vector interactions. This difference is a reflection of the different dimensions of the two effective operators.

C. Indirect detection

Compared with the direct search method for the WIMP DM at underground laboratories on Earth, an indirect detection method concerning astrophysical effects of DM is relatively independent and complementary. This method is used to look for the DM annihilation or decay products which include gamma rays, neutrinos, positrons, antiprotons and so on. These particles can be detected by satellite, ground and underground cosmic ray experiments. When propagating in the Galaxy, the charged products are deflected by Galactic magnetic fields and interact with interstellar medium. Therefore we have to consider the propagation process of the charged particles in order to compare predictions with observations.

FIG. 4. The 3σ upper bounds on the coupling constants F_f from the PAMELA $\bar{p}/p$ ratio [67] in each complex scalar WIMP effective model. In the left (right) column, results are given for the case of universal couplings ($F_f \propto m_f$).

The propagation equation of cosmic rays in the Galaxy can be written down as [74]

$$\frac{\partial \psi}{\partial t} = Q(\mathbf{r}, p) + \nabla \cdot (D_{xx} \nabla \psi - \mathbf{V}_c \psi) + \frac{\partial}{\partial p} \left[p^2 D_{pp} \frac{\partial}{\partial p} \left(\frac{1}{p^2} \psi \right) \right] - \frac{\partial}{\partial p} \left[\dot{p} \psi - \frac{p}{3} (\nabla \cdot \mathbf{V}_c) \psi \right] - \frac{1}{\tau_f} \psi - \frac{1}{\tau_r} \psi, \quad (20)$$

where $\psi = \psi(\mathbf{r}, p, t)$ is the number density of cosmic-ray particles per unit momentum interval, $Q(\mathbf{r}, p)$ is the source term, D_{xx} is the spatial diffusion coefficient, $\mathbf{V}_c$ is the convection velocity, D_{pp} is the diffusion coefficient in momentum space describing the reacceleration process, $\dot{p} \equiv dp/dt$ is the momentum loss rate, τ_f and τ_r are the time scales for fragmentation and the radioactive decay, respectively. Following our previous work [50] we consider the antiproton-to-proton flux ratio $\bar{p}/p$ measured by the satellite-borne experiment PAMELA [67] to constrain the effective models. To proceed we solve the propagation equation (20) by the numerical code GALPROP [74] and compare the solution to the PAMELA $\bar{p}/p$ data.

The source term of $\bar{p}$ induced by the annihilation of complex scalar WIMPs is given by

$$Q_{\text{ann}}(\mathbf{r}, E) = \frac{\langle \sigma_{\text{ann}} v \rangle_{\text{tot}}}{4M_\phi^2} \left[\sum_q B_q \left(\frac{dN_{\bar{p}}}{dE_{\bar{p}}} \right)_q \right] \rho^2(\mathbf{r}), \quad q = u, d, s, c, b, t, \quad (21)$$

where $\langle \sigma_{\text{ann}} v \rangle_{\text{tot}}$ is the total annihilation rate of WIMPs to quarks, B_q is the branching ratio of each $\bar{q}q$ channel, $\rho(\mathbf{r})$ is the mass density distribution of the Galactic DM halo, $(dN_{\bar{p}}/dE_{\bar{p}})_q$ is the number per unit energy interval of the antiprotons produced by a WIMP pair-annihilation in the $\bar{q}q$ channel. In particular, $(dN_{\bar{p}}/dE_{\bar{p}})_q$ is calculated by the Monte Carlo code PYTHIA [75]. For real scalar WIMPs, the factor $\langle \sigma_{\text{ann}} v \rangle_{\text{tot}} / 4M_\phi^2$ in Eq. (21) is modified to $\langle \sigma_{\text{ann}} v \rangle_{\text{tot}} / 2M_\phi^2$ since the two annihilating WIMP are indistinguishable.

The NFW profile [76] is taken to describe $\rho(\mathbf{r})$ with the characteristic density $\rho_s = 0.334 \text{ GeV cm}^3$ and the scale radius $r_s = 20 \text{ kpc}$, which leads to a local DM density $\rho(8.33 \text{ kpc}) = 0.4 \text{ GeV cm}^{-3}$. The DM particles in the Galactic halo obey the Maxwell-Boltzmann velocity distribution $f(v_0) = (M_\phi / 2\pi k_B T)^{3/2} \exp(-M_\phi v_0^2 / 2k_B T)$. Their velocity dispersion $\bar{v}_0 \equiv \sqrt{\langle v_0^2 \rangle} = \sqrt{3T/M_\phi}$ is taken to be the canonical value 270 km s^{-1} [5]. In the calculation

of the $\bar{p}/p$ spectrum with GALPROP, the Galaxy propagation model with diffusion and convection is adopted and the half-height of the Galaxy propagation halo z_h is set to be 4 kpc. The PAMELA $\bar{p}/p$ spectrum is best fitted by astrophysical background with a solar modulation potential of $\Phi = 335$ MV, which gives the minimal χ^2 . Under such potential if the contribution of DM is added in, the resulted spectrum deviates from the background and gives a larger χ^2 . Thus for the fixed M_ϕ in both the cases of universal couplings and $F_f \propto m_f$ for each type of effective interactions, we can derive the 3σ upper bounds on $\langle\sigma_{\text{ann}}v\rangle_{\text{tot}}$, which eventually set the bounds on effective coupling constants F_f , as shown in Fig. 4.

In Fig. 4, the upper bounds set for S and SP interactions and those for V and VA interactions are nearly identical respectively, with slight differences at $M_\phi \sim m_t$ in the case of $F_f \propto m_f$. The reason is the same as that explained in Subsection II A. It is also worth noting that the upper bound curves for the operators with different dimensions have different trends of slope, due to the additional factor M_ϕ^2 in the annihilation cross sections of dimension-6 operators (V and VA). For the case of $F_f \propto m_f$, downward bends at $M_\phi \sim m_t$ in the curves appear again, because of the $\phi\phi^\dagger \rightarrow t\bar{t}$ threshold effect.

FIG. 5. Combined constraints on coupling constants F_f of complex scalar WIMPs with scalar (S) interaction from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The yellow region denotes the invalid parameter space of effective field theory. The left (right) frame is shown for the case of universal couplings ($F_f \propto m_f$).

FIG. 6. Combined constraints on coupling constants F_f of complex scalar WIMPs with vector (V) interaction from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 7. Combined constraints on coupling constants F_f of complex scalar WIMPs with scalar-pseudoscalar (SP) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 8. Combined constraints on coupling constants F_f of complex scalar WIMPs with vector-axialvector (VA) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

D. Validity region of effective models and combined constraints

In this subsection, we will discuss the validity region where the method of effective theory can be used. Since our previous analysis is made in both the cases of universal couplings and $F_f \propto m_f$, we consider them case by case in the following.

- In the case of universal couplings, for dimension-5 operators S and SP (dimension-6 operators V and VA), F_f can be written as $F_f/\sqrt{2} = \alpha/\Lambda$ ($F_f/\sqrt{2} = \alpha/\Lambda^2$), where Λ is the cutoff energy scale and α is the coupling of the fundamental theory beyond Λ , which may be of order 1. The transfer momentum of the annihilation process $\phi\phi^\dagger \rightarrow f\bar{f}$ must be well below the cutoff, i.e., $2M_\phi \ll \Lambda$, so that the effective theory can be used. On the other hand, a weakly coupled UV completion of the effective theory usually requires $\alpha < 4\pi$ such that the perturbative method is valid [47, 77]. From the above 3 relations, we obtain

$$F_f \ll \frac{2\sqrt{2}\pi}{M_\phi}, \quad \text{for S and SP interactions,} \quad (22)$$

$$F_f \ll \frac{\sqrt{2}\pi}{M_\phi^2}, \quad \text{for V and VA interactions.} \quad (23)$$

- In the case of $F_f \propto m_f$, for dimension-5 operators S and SP (dimension-6 operators V and VA), F_f can be written as $F_f/\sqrt{2} = \alpha m_f/\Lambda^2$ ($F_f/\sqrt{2} = \alpha m_f/\Lambda^3$). Likewise, we still have $2M_\phi \ll \Lambda$ and $\alpha < 4\pi$. From the above 3 relations, we obtain

$$\frac{F_f}{m_f} \ll \frac{\sqrt{2}\pi}{M_\phi^2}, \quad \text{for S and SP interactions,} \quad (24)$$

$$\frac{F_f}{m_f} \ll \frac{\pi}{\sqrt{2}M_\phi^3}, \quad \text{for V and VA interactions.} \quad (25)$$

TABLE I. A summary for complex scalar WIMPs with various effective interactions. The excluded regions of M_ϕ given by direct and indirect experiments are indicated.

Universal coupling		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_\phi \simeq 10$ GeV – above 1 TeV	Excluded $M_\phi \simeq 10 - 73$ GeV
V	Excluded $M_\phi \simeq 10$ GeV – above 1 TeV	Not sensitive
SP	Not sensitive	Excluded $M_\phi \simeq 10 - 73$ GeV
VA	Not sensitive	Not sensitive
$F_f \propto m_f$		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_\phi \simeq 10 - 168$ GeV	Excluded $M_\phi \simeq 10 - 73$ GeV
V	Excluded $M_\phi \simeq 10 - 100$ GeV	Not sensitive
SP	Not sensitive	Excluded $M_\phi \simeq 10 - 73$ GeV
VA	Not sensitive	Not sensitive

Considering the validity conditions (22) – (25) altogether with the other phenomenological constraints, we derive the combined constraints on the effective models. In Figs. 5 and 6 we show the combined constraints on coupling constants F_f of complex scalar WIMPs with S and V interactions from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio and validity of effective theory, while in Figs. 7 and 8, we show the combined constraints on F_f with SP and VA interactions from relic density, PAMELA $\bar{p}/p$ ratio and validity of effective theory. The invalid parameter space of effective field theory is denoted by the yellow region in each figure. The constraints are much similar between S and SP interactions, and so are those between V and VA interactions, except that the S and V interactions are constrained by direct detection experiments, while the SP and VA interactions are not.

There are some interesting features in Figs. 5 – 8. In the case of universal coupling for S and V interactions, the WIMP with $M_\phi < 1$ TeV are strongly excluded by direct detection experiments, while in the case of $F_f \propto m_f$, the direct detection exclude a much smaller range of M_ϕ . The indirect detection constraints also rule out the WIMP with $M_\phi \lesssim 70$ GeV for S and SP interactions, while the constraints becomes much weaker for V and VA interactions. The reason is that for V and VA interactions the annihilation rate (10) and (12) are of order $\mathcal{O}(T/M_\phi)$, which lead to looser bounds by indirect detection because of the much lower WIMP temperature today comparing with that of the WIMP freeze-out epoch. Additionally, in the case of $F_f \propto m_f$ the effective interactions are valid only up to $M_\phi \sim \text{TeV}$. A larger WIMP mass in these cases may implies violation to our previous assumptions, such as the existence of a light intermediate state, or the effect of resonances or coannihilations.

If the effective coupling is much weaker than that derived from the observed relic density, the thermal DM production may overclose the Universe. Therefore the DM models in which the direct or indirect detection constraints are stronger than that of relic density should be excluded, or else some exotic entropy generation processes should occur after DM froze out. As a summary of the study on the scalar WIMP, in Table I, we indicate the excluded regions of M_ϕ given by direct and indirect experiments for complex scalar WIMPs with various effective interactions.

III. VECTOR DARK MATTER

In this section, we will discuss the case that DM consists of complex vector WIMPs (X^μ and its antiparticle $X^{\mu*}$). Notable differences between this case and the case of real vector WIMPs will be remarked below. Following the procedure in which we discuss scalar WIMPs in Section II, we construct effective interaction operators of $X^{\mu*}$ - X^ν - $\bar{f}$ - f type between the WIMPs and the SM fermions, which are limited only by the requirements of Hermiticity, Lorentz invariance and CPT invariance.

The assumptions listed in Section II are also adopted. Thus the effective interaction term of Lagrangian between two complex vector WIMPs (X^μ and $X^{\mu*}$) and two SM fermions (f and $\bar{f}$) is given by only one of the following expressions:

$$\text{Scalar int. (S) : } \mathcal{L}_S = \sum_f \frac{K_{S,f}}{\sqrt{2}} X_\mu^* X^\mu \bar{f} f, \quad (26)$$

$$\text{Vector int. (V) : } \mathcal{L}_V = \sum_f \frac{K_{V,f}}{\sqrt{2}} (X_\nu^* i \overleftrightarrow{\partial}_\mu X^\nu) \bar{f} \gamma^\mu f, \quad (27)$$

$$\text{Tensor int. (T) : } \mathcal{L}_T = \sum_f \frac{K_{T,f}}{\sqrt{2}} i (X_\mu^* X_\nu - X_\nu^* X_\mu) \bar{f} \sigma^{\mu\nu} f, \quad (28)$$

$$\text{Scalar-Pseudoscalar int. (SP) : } \mathcal{L}_{SP} = \sum_f \frac{K_{SP,f}}{\sqrt{2}} X_\mu^* X^\mu \bar{f} i \gamma_5 f, \quad (29)$$

$$\text{Vector-Axialvector int. (VA) : } \mathcal{L}_{VA} = \sum_f \frac{K_{VA,f}}{\sqrt{2}} (X_\nu^* i \overleftrightarrow{\partial}_\mu X^\nu) \bar{f} \gamma^\mu \gamma_5 f, \quad (30)$$

$$\text{Alternative Vector int. (\tilde{V}) : } \mathcal{L}_{\tilde{V}} = \sum_f \frac{\tilde{K}_{V,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} (X_\mu^* \overleftrightarrow{\partial}_\nu X_\rho) \bar{f} \gamma_\sigma f, \quad (31)$$

$$\text{Alternative Vector-Axialvector int. (\tilde{VA}) : } \mathcal{L}_{\tilde{VA}} = \sum_f \frac{\tilde{K}_{VA,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} (X_\mu^* \overleftrightarrow{\partial}_\nu X_\rho) \bar{f} \gamma_\sigma \gamma_5 f, \quad (32)$$

$$\text{Alternative Tensor int. (\tilde{T}) : } \mathcal{L}_{\tilde{T}} = \sum_f \frac{\tilde{K}_{T,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} i (X_\mu^* X_\nu - X_\nu^* X_\mu) \bar{f} \sigma_{\rho\sigma} f, \quad (33)$$

where the sum of f is over all the SM fermions, and the effective coupling constants K_f are real numbers. For the dimension-5 operators (S, SP, T and $\tilde{T}$), the coupling constants K_f have mass dimension of -1 , while for the dimension-6 operators (V, VA, $\tilde{V}$ and $\tilde{VA}$), K_f have mass dimension of -2 . Operators with more derivatives on the fields are not considered, since such operators are more suppressed at low energy scale due to their higher mass dimensions. Note that for the case of real vector WIMPs, the V, T, VA and $\tilde{T}$ interactions vanish. In the following, we will discuss the phenomenological constraints on K_f given by the recent results of the DM relic density, direct and indirect detection experiments.

A. Vector WIMP annihilation and relic density

In order to calculate relic density and DM contribution in cosmic ray, the annihilation cross sections of WIMP-antiWIMP to SM fermion-antifermion pairs are needed. For each effective model listed above, the result is given by

$$\sigma_{S, \text{ann}} = \frac{1}{288\pi M_X^4} \sum_f \left(\frac{K_{S,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_X^2}} \frac{(s - 4m_f^2)(s^2 - 4M_X^2 s + 12M_X^4)}{s}, \quad (34)$$

$$\sigma_{V, \text{ann}} = \frac{1}{432\pi M_X^4} \sum_f \left(\frac{K_{V,f}}{\sqrt{2}} \right)^2 c_f \sqrt{(s - 4m_f^2)(s - 4M_X^2)} \frac{(s + 2m_f^2)(s^2 - 4M_X^2 s + 12M_X^4)}{s}, \quad (35)$$

$$\sigma_{T, \text{ann}} = \frac{1}{216\pi M_X^4} \sum_f \left(\frac{K_{T,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_X^2}} \left[s^2 + (8m_f^2 + 4M_X^2)s - 16m_f^2 M_X^2 - 8M_X^4 - 160 \frac{m_f^2 M_X^4}{s} \right], \quad (36)$$

FIG. 9. The predicted coupling constants K_f as functions of the vector WIMP mass M_X , fixed by the observed relic density, $\Omega_{\text{DM}} h^2 = 0.1109 \pm 0.0056$ [3]. Frames in the left (right) column are results given for the case of universal couplings ($K_f \propto m_f$).

$$\sigma_{\text{SP, ann}} = \frac{1}{288\pi M_X^4} \sum_f \left(\frac{K_{\text{SP},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_X^2}} (s^2 - 4M_X^2 s + 12M_X^4), \quad (37)$$

$$\sigma_{\text{VA, ann}} = \frac{1}{432\pi M_X^4} \sum_f \left(\frac{K_{\text{VA},f}}{\sqrt{2}} \right)^2 c_f \sqrt{(s - 4m_f^2)(s - 4M_X^2)} \frac{(s - 4m_f^2)(s^2 - 4M_X^2 s + 12M_X^4)}{s}, \quad (38)$$

$$\sigma_{\tilde{\text{V}}, \text{ann}} = \frac{1}{108\pi M_X^2} \sum_f \left(\frac{\tilde{K}_{\text{V},f}}{\sqrt{2}} \right)^2 c_f \sqrt{(s - 4m_f^2)(s - 4M_X^2)} \frac{(s - 4M_X^2)(s + 2m_f^2)}{s}, \quad (39)$$

$$\sigma_{\tilde{\text{VA}}, \text{ann}} = \frac{1}{108\pi M_X^2} \sum_f \left(\frac{\tilde{K}_{\text{VA},f}}{\sqrt{2}} \right)^2 c_f \sqrt{(s - 4m_f^2)(s - 4M_X^2)} \left[s - 4(M_X^2 + m_f^2) + 28 \frac{m_f^2 M_X^2}{s} \right], \quad (40)$$

$$\sigma_{\tilde{\text{T}}, \text{ann}} = \frac{1}{54\pi M_X^4} \sum_f \left(\frac{\tilde{K}_{\text{T},f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s - 4m_f^2}{s - 4M_X^2}} \left[s^2 + 4(M_X^2 - m_f^2)s + 32m_f^2 M_X^2 - 8M_X^4 + 128 \frac{m_f^2 M_X^4}{s} \right], \quad (41)$$

where M_X is the WIMP mass. For the case of real vector WIMPs, each non-vanishing annihilation cross section should include an additional factor of 4 because the WIMP and its antipartner are identical. After taking the thermal average, we obtain the annihilation rates, i.e.,

$$\langle \sigma_{\text{S, ann}} v \rangle \simeq \frac{1}{12\pi} \sum_f \left(\frac{K_{\text{S},f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} \left[\left(1 - \frac{m_f^2}{M_X^2} \right) + \frac{1}{4} \left(2 + 7 \frac{m_f^2}{M_X^2} \right) \frac{T}{M_X} \right], \quad (42)$$

$$\langle \sigma_{\text{V, ann}} v \rangle \simeq \frac{1}{6\pi} \sum_f \left(\frac{K_{\text{V},f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} M_X^2 \left(2 + \frac{m_f^2}{M_X^2} \right) \frac{T}{M_X}, \quad (43)$$

FIG. 10. The predicted thermal relic density (dashed lines) of complex vector WIMPs with S, V, T, $\tilde{T}$, $\tilde{V}$ and $\tilde{V}A$ interactions, respectively. In the upper two frames, results are shown for the case of $K_f \propto m_f$ with S and V interactions. In the remaining frames, results are given for the case of universal couplings. The narrow horizontal solid band shows the range of the observed DM relic density, $\Omega_{DM} h^2 = 0.1109 \pm 0.0056$ [3].

$$\langle \sigma_{T, \text{ann}} v \rangle \simeq \frac{1}{18\pi} \sum_f \left(\frac{K_{T,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} \left[4 \left(1 - \frac{m_f^2}{M_X^2} \right) + 3 \left(2 + 9 \frac{m_f^2}{M_X^2} \right) \frac{T}{M_X} \right], \quad (44)$$

$$\langle \sigma_{\text{SP}, \text{ann}} v \rangle \simeq \frac{1}{12\pi} \sum_f \left(\frac{K_{\text{SP},f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} \left[1 + \frac{2 + m_f^2/M_X^2}{4(1 - m_f^2/M_X^2)} \frac{T}{M_X} \right], \quad (45)$$

$$\langle \sigma_{\text{VA}, \text{ann}} v \rangle \simeq \frac{1}{3\pi} \sum_f \left(\frac{K_{\text{VA},f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_X^2} \right)^{3/2} M_X^2 \frac{T}{M_X}, \quad (46)$$

$$\langle \sigma_{\tilde{V}, \text{ann}} v \rangle \simeq \frac{5}{9\pi} \sum_f \left(\frac{\tilde{K}_{V,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} M_X^2 \left(2 + \frac{m_f^2}{M_X^2} \right) \frac{T^2}{M_X^2}, \quad (47)$$

$$\langle \sigma_{\tilde{\text{VA}}, \text{ann}} v \rangle \simeq \frac{1}{3\pi} \sum_f \left(\frac{\tilde{K}_{\text{VA},f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} m_f^2 \frac{T}{M_X}, \quad (48)$$

$$\langle \sigma_{\tilde{T}, \text{ann}} v \rangle \simeq \frac{1}{9\pi} \sum_f \left(\frac{\tilde{K}_{T,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_X^2}} \left[8 \left(1 + 2 \frac{m_f^2}{M_X^2} \right) + \frac{6(2 - 5m_f^2/M_X^2)(1 - 2m_f^2/M_X^2)}{1 - m_f^2/M_X^2} \frac{T}{M_X} \right]. \quad (49)$$

Note that in the case of $\tilde{V}$ interaction, $\langle \sigma_{\text{ann}} v \rangle$ vanishes in the zeroth and the first orders of T/M_X , thus we retain the term of order T^2/M_X^2 .

The procedure to obtain the relic density of vector WIMPs is similar to that in the case of scalar WIMPs. A notable difference is that the degree of freedom for a vector WIMP is $g = 3$. Besides, since $\langle \sigma_{\text{ann}} v \rangle$ of $\tilde{V}$ interaction (47) is of order T^2/M_X^2 , Eqs. (14) and (15) need to be extended. If $\sigma_{\text{ann}} v$ in the lab frame is expanded to be $\sigma_{\text{ann}} v \simeq a_0 + a_1 v^2 + a_2 v^4 + \mathcal{O}(v^6)$, we have $\langle \sigma_{\text{ann}} v \rangle \simeq a_0 + 6a_1 x^{-1} + (60a_2 - 27a_1)x^{-2} + \mathcal{O}(x^{-3})$ with $x \equiv M_X/T$. Then the factor $(a_0 + 3a_1 x_f^{-1})$ in the denominator of the right-hand side of Eq. (14) should be modified to be $[a_0 + 3a_1 x_f^{-1} + (20a_2 - 9a_1)x_f^{-2}]$, and the factor $(a_0 + 6a_1 x_f^{-1})$ in the square bracket of the right-hand side of Eq. (15) should be modified to be $[a_0 + 6a_1 x_f^{-1} + (60a_2 - 27a_1)x_f^{-2}]$. For the case of real vector WIMPs, the relic density just one half of that for the case of complex vector WIMPs given the same annihilation cross section.

In Fig. 9, the predicted coupling constants K_f fixed by the WMAP observed relic density are shown as functions of M_X . The upper two frames are plotted for dimension-5 operators (S, SP, T and $\tilde{T}$), while the remaining two are plotted for dimension-6 operators (V, VA, $\tilde{V}$ and $\tilde{\text{VA}}$). Two cases of coupling constants are considered again. In the left (right) column of the frames, results are given for universal couplings ($K_f \propto m_f$). There are some interesting features in Fig. 9:

- The curves for the case of $K_f \propto m_f$ have sharp downward bends at $M_X \sim m_t$. The reason is the same as that in the case of scalar WIMPs. Even for the case of universal couplings, the curve of $\tilde{\text{VA}}$ interaction also exhibits the same bending behavior because of $\langle \sigma_{\tilde{\text{VA}}, \text{ann}} v \rangle \propto m_f^2$.
- There are two pairs of nearly identical curves, $S \simeq \text{SP}$ and $V \simeq \text{VA}$. This is because of the similarities of the annihilation rates corresponding to these two pairs of interactions, respectively. The leading terms of these two pairs of the annihilation rates tend to be the same when M_X is much larger than that of the final state fermions.
- The curves of V and VA interactions are obviously lower than the other two curves of $\tilde{V}$ and $\tilde{\text{VA}}$ interactions. That is due to the forms of the annihilation rates. The leading terms of the annihilation rates for V and VA interactions are of order T/M_X , while that for $\tilde{V}$ interaction is of order T^2/M_X^2 . The leading term of the annihilation rate for $\tilde{\text{VA}}$ interaction is proportional to $m_f^2 T/M_X$, which is suppressed by the SM fermion masses m_f that are smaller than M_X almost in the whole region. On the other hand, the curves of T and $\tilde{T}$ interactions are lower than those of S and SP interactions due to the larger zeroth order terms of the annihilation rates for T and $\tilde{T}$ interactions.

In Fig. 10, we show the predicted thermal relic density $\Omega_{\text{DM}} h^2$ of complex vector WIMPs for S, V, T, $\tilde{T}$, $\tilde{V}$ and $\tilde{\text{VA}}$ interactions. The curves for SP and VA interactions are very similar to those for S and V interactions respectively, as discussed above. In the upper two frames, results are shown for the case of $K_f \propto m_f$ with S and V interactions. The remaining frames give the results for the case of universal couplings. Similar to the case of scalar WIMPs, the curves for dimension-5 operators (S, SP, T and $\tilde{T}$) are nearly horizontal in almost the whole mass range, while those for

dimension-6 operators slope downward (except for those of $\widetilde{\text{VA}}$ interaction, due to $\langle \sigma_{\widetilde{\text{VA}}, \text{ann}} v \rangle \propto m_f^2$). Additionally, if resonances, coannihilations, or annihilations to final states other than fermion-antifermion pairs are significant, the actual curves in Figs. 9 and 10 will be significantly lower than they are shown there.

B. Direct detection and indirect detection

In this subsection we discuss the direct and indirect detection constraints on the effective vector WIMP models described by Eqs. (26) – (33). In the low velocity limit, only the scattering cross sections of S, V, T and $\widetilde{\text{VA}}$ interactions survive, and others are suppressed by the low WIMP velocity. The S and V interactions between WIMPs and nuclei are spin-independent (SI), while the T and $\widetilde{\text{VA}}$ interactions are spin-dependent (SD). In order to be compared with the results of CDMS [59][60] and XENON [61][62], the WIMP-nucleon cross sections are given as follows:

$$\text{Scalar int. : } \sigma_{\text{S}, XN} = \frac{m_N^2}{4\pi (M_X + m_N)^2} \left(\frac{K_{\text{S}, N}}{\sqrt{2}} \right)^2, \quad (50)$$

$$\text{Vector int. : } \sigma_{\text{V}, XN} = \frac{m_N^2 M_X^2}{\pi (M_X + m_N)^2} \left(\frac{K_{\text{V}, N}}{\sqrt{2}} \right)^2, \quad (51)$$

$$\text{Tensor int. : } \sigma_{\text{T}, XN} = \frac{2m_N^2}{\pi (M_X + m_N)^2} \left(\frac{K_{\text{T}, N}}{\sqrt{2}} \right)^2, \quad (52)$$

$$\widetilde{\text{VA}} \text{ int. : } \sigma_{\widetilde{\text{VA}}, XN} = \frac{2m_N^2 M_X^2}{\pi (M_X + m_N)^2} \left(\frac{\tilde{K}_{\text{VA}, N}}{\sqrt{2}} \right)^2, \quad (53)$$

where K_N ($N = p, n$) are the induced coupling constants of effective WIMP-nucleon interactions, related to the couplings of WIMP-quark K_q by form factors. For S and V interactions, the relations between K_N and K_q are the same as those between F_N and F_q (Eqs. (18) and (19)), respectively. For $\widetilde{\text{VA}}$ and T interactions,

$$\tilde{K}_{\text{VA}, N} = \sum_{q=u,d,s} \tilde{K}_{\text{VA}, q} \Delta_q^N, \quad (54)$$

$$K_{\text{T}, N} = \sum_{q=u,d,s} K_{\text{T}, q} \Delta_q^N, \quad (55)$$

with the form factors $\Delta_u^p = 0.842 \pm 0.012$, $\Delta_d^p = -0.427 \pm 0.013$, $\Delta_s^p = -0.085 \pm 0.018$ [78], $\Delta_u^n = \Delta_d^p$, $\Delta_d^n = \Delta_u^p$, $\Delta_s^n = \Delta_s^p$, which reflect the contributions of quark components to the nucleon spin. Note again for real vector WIMPs, the V and T interactions vanish, and the scattering cross sections of S and $\widetilde{\text{VA}}$ interactions should include an additional factor 4 comparing to the case of complex vector WIMPs.

To compare with the searching bounds of direct detection experiments, we plot the predicted σ_{XN} vs. M_X curves with fixed couplings. In Fig. 11, the spin-dependent WIMP-proton cross sections (dashed lines) for S and V interactions are shown. In the left (right) column, results are given for universal couplings ($K_f \propto m_f$). The upper bounds set by CDMS II [59] and XENON100 [61] are also given in the frames. In Fig. 12, the spin-dependent (SD) WIMP-neutron cross sections (dashed lines) for $\widetilde{\text{VA}}$ and T interactions are shown. In the left (right) column, results are given for universal couplings ($K_f \propto m_f$). The upper bounds set by CDMS [60] and XENON10 [62] are also given in the frames.

From Figs. 11 and 12, we find that the experimental constraints are much stronger for SI interactions than those for SD interactions, since the scattering amplitudes between WIMPs and nucleons in the nuclei add coherently in the case of SI interactions. Additionally, the curves for dimension-5 operators (S and T) slope downward, while those for dimension-6 operators (V and $\widetilde{\text{VA}}$) remain horizontal in most range of mass. This is due to an additional factor of M_X^2 in Eqs. (51) and (53) comparing with Eqs. (50) and (52).

The calculation of indirect detection constraints of vector WIMPs is totally similar to that of scalar WIMPs in Subsection II C. In Fig. 13, we show the 3σ upper bounds on the coupling constants F_f from the PAMELA $\bar{p}/p$ ratio [67] in each effective complex vector WIMP model for the cases of universal couplings and $K_f \propto m_f$.

Due to the similar reasons, the bounds in Fig. 13 have similar properties as the relic density bounds in Subsection III A: (a) There are sharp downward bends in the curves at $M_X \sim m_t$ when $\langle \sigma_{\text{ann}} v \rangle \propto m_f^2$ or $\propto m_f^4$. (b) There are two pairs of interactions that have almost the identical bounds, $\text{S} \simeq \text{SP}$ and $\text{V} \simeq \text{VA}$. (c) The curves of S and SP interactions lie well above those of T and $\widetilde{\text{T}}$ interactions, while the curves of V and VA interactions lie well below those of $\widetilde{\text{V}}$ and $\widetilde{\text{VA}}$ interactions. Again, we can find the explanations to these features in the annihilation rates Eqs. (42) – Eq. (49).

FIG. 11. The spin-independent (SI) WIMP-proton cross sections (dashed lines) for complex vector WIMPs with S and V interactions. In the left (right) column, results are given for universal couplings ($K_f \propto m_f$). The upper bounds set by CDMS II [59] and XENON100 [61] are also given in the frames for comparison.

FIG. 12. The spin-dependent (SD) WIMP-neutron cross sections (dashed lines) for complex vector WIMPs with $\tilde{V}\tilde{A}$ and T interactions. In the left (right) column, results are given for universal couplings ($K_f \propto m_f$). The upper bounds set by CDMS [60] and XENON10 [62] are also given in the frames for comparison.

C. Validity region of effective models and combined constraints

Since we are using effective theory, we can only carry out our analysis below an energy cutoff scale Λ , which leads to validity bounds on the effective couplings K_f if the perturbative theory is assumed for UV completion, as we discussed in Subsection II D. Then for the case of universal couplings, we have

$$K_f \ll \frac{2\sqrt{2}\pi}{M_X}, \quad \text{for S, SP, T and } \tilde{T} \text{ interactions,} \quad (56)$$

$$K_f \ll \frac{\sqrt{2}\pi}{M_X^2}, \quad \text{for V, VA, } \tilde{V} \text{ and } \tilde{V}\tilde{A} \text{ interactions.} \quad (57)$$

On the other hand, for the case of $K_f \propto m_f$ we obtain

$$\frac{K_f}{m_f} \ll \frac{\sqrt{2}\pi}{M_X^2}, \quad \text{for S, SP, T and } \tilde{T} \text{ interactions,} \quad (58)$$

$$\frac{K_f}{m_f} \ll \frac{\pi}{\sqrt{2}M_X^3}, \quad \text{for V, VA, } \tilde{V} \text{ and } \tilde{V}\tilde{A} \text{ interactions.} \quad (59)$$

Considering the validity conditions (56) – (59) altogether with other phenomenological constraints, we obtain the combined constraints on the effective vector WIMP models. In Figs. 14 – 19, the combined constraints of the effective models of S, V, T, $\tilde{V}$, $\tilde{V}\tilde{A}$ and $\tilde{T}$ interactions are shown, with the yellow regions denoting the invalid parameter spaces of effective field theory. The constraints on SP and VA interactions are very similar to those on S and V interactions respectively, except that the SP and VA interactions are not constrained by direct detection experiments. S and V interactions with universal couplings are stringently constrained by direct detection experiments, while the constraints for the case of $K_f \propto m_f$ are much looser. The direct detection bounds for SD interactions (T and $\tilde{V}\tilde{A}$) is so much looser

FIG. 13. The 3σ upper bounds on the coupling constants K_f from the PAMELA $\bar{p}/p$ ratio [67] in each effective complex vector WIMP model. In the left (right) column, results are given for universal couplings ($K_f \propto m_f$).

than those for SI interactions (S and V) that they only exclude a region of small mass in the case of $\widetilde{VA}$ interaction with universal couplings. The constraints by PAMELA $\bar{p}/p$ ratio exclude the mass regions of $M_X \lesssim 70$ GeV for dimension-5 operators (S, SP, T and $\widetilde{T}$), while those for dimension-6 operators (V, VA, $\widetilde{V}$ and $\widetilde{VA}$) are much weaker. The reason is that for dimension-6 operators, the annihilation rates Eqs. (43), (46), (47) and (48) are of order T/M_X or T^2/M_X^2 , which lead to much looser bounds by indirect detection because the WIMP temperature today is much lower than that of the WIMP freeze-out epoch. In the cases of $\widetilde{V}$ and $\widetilde{VA}$ interactions with $K_f \propto m_f$, large parts of the curves set by relic density lie in the invalid regions of effective theory, which may indicate effects of resonances, coannihilations, light intermediate states, or final states other than SM fermion pairs.

FIG. 14. Combined constraints on coupling constants K_f of complex vector WIMPs with scalar (S) interaction from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The yellow region denotes the invalid parameter space of effective field theory. The left (right) frame is shown for the case of universal couplings ($K_f \propto m_f$). The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for scalar-pseudoscalar (SP) interaction are very similar to those for scalar interaction, but direct detection experiments are not sensitive to SP interaction.

FIG. 15. Combined constraints on coupling constants K_f of complex vector WIMPs with vector (V) interaction from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for vector-axialvector (VA) interaction are very similar to those for vector interaction, but direct detection experiments are not sensitive to VA interaction.

As a summary of the study on the vector WIMP, in Table II, the excluded regions of M_X given by direct and indirect experiments for complex vector WIMPs with various effective interactions are shown.

IV. SPIN-3/2 DARK MATTER

In this section, we will extend our discuss to the case that DM consists of spin-3/2 fermionic WIMPs. The spin-3/2 WIMP can be described by a vector-spinor χ_α^μ which carries both a vector index μ and a spinor index α . Then a free

FIG. 16. Combined constraints on coupling constants K_f of complex vector WIMPs with tensor (T) interaction from relic density, direct detection experiments of CDMS and XENON10, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 17. Combined constraints on coupling constants K_f of complex vector WIMPs with alternative vector ($\tilde{V}$) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 18. Combined constraints on coupling constants K_f of complex vector WIMPs with alternative vector-axialvector ($\tilde{V}\tilde{A}$) interaction from relic density, direct detection experiments of CDMS and XENON10, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

WIMP satisfies the rank-1 Rarita-Schwinger equations [79]

$$(i\not{\partial} - M_\chi)\chi^\mu = 0, \quad \gamma_\mu\chi^\mu = 0, \quad (60)$$

FIG. 19. Combined constraints on coupling constants K_f of complex vector WIMPs with alternative tensor ($\tilde{T}$) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

TABLE II. A summary for complex vector WIMPs with various effective interactions. The excluded regions of M_X given by direct and indirect experiments are indicated.

Universal coupling		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_X \simeq 10$ GeV – above 1 TeV	Excluded $M_X \simeq 10 - 74$ GeV
V	Excluded $M_X \simeq 10$ GeV – above 1 TeV	Not sensitive
T	Not sensitive	Excluded $M_X \simeq 10 - 71$ GeV
SP	Not sensitive	Excluded $M_X \simeq 10 - 73$ GeV
VA	Not sensitive	Not sensitive
$\tilde{V}$	Not sensitive	Not sensitive
$\tilde{VA}$	Excluded $M_X \simeq 10 - 170$ GeV	Not sensitive
$\tilde{T}$	Not sensitive	Excluded $M_X \simeq 10 - 72$ GeV
$K_f \propto m_f$		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_X \simeq 10 - 172$ GeV	Excluded $M_X \simeq 10 - 74$ GeV
V	Excluded $M_X \simeq 10 - 157$ GeV	Not sensitive
T	Not sensitive	Excluded $M_X \simeq 10 - 70$ GeV
SP	Not sensitive	Excluded $M_X \simeq 10 - 74$ GeV
VA	Not sensitive	Not sensitive
$\tilde{V}$	Not sensitive	Not sensitive
$\tilde{VA}$	Not sensitive	Not sensitive
$\tilde{T}$	Not sensitive	Excluded $M_X \simeq 10 - 72$ GeV

where the spinor indices have been suppressed. From Eqs. (60), it can be seen that each component of χ^μ acts as a Dirac spinor, while all the four components together are constrained by the subsidiary condition $\gamma_\mu \chi^\mu = 0$. By introducing an orthogonal spin projection operator, the spin sum relations in momentum space can be derived [80, 81], i.e.,

$$\sum_{s=1}^4 u_s^\mu(p) \bar{u}_s^\nu(p) = (\not{p} + M_\chi) \left(P^{\mu\nu} - \frac{1}{3} P^{\mu\rho} P^{\nu\sigma} \gamma_\rho \gamma_\sigma \right), \quad (61)$$

$$\sum_{s=1}^4 v_s^\mu(p) \bar{v}_s^\nu(p) = (\not{p} - M_\chi) \left(P^{\mu\nu} - \frac{1}{3} P^{\mu\rho} P^{\nu\sigma} \gamma_\rho \gamma_\sigma \right), \quad (62)$$

where s is the spin index, and $u_s^\mu(p)$ ($v_s^\mu(p)$) are the positive (negative) energy solutions of Eqs. (60), and $P^{\mu\nu} \equiv g^{\mu\nu} - p^\mu p^\nu / p^2$.

Although spin-3/2 field theories suffer from a common problem of non-renormalizability, it is safe to consider effective field theory below an appropriate energy cutoff. Following the assumptions in Sections II and III, we construct the effective interaction operators of $\bar{\chi}^\mu\text{-}\chi^\nu\text{-}f\text{-}f$ type between the WIMPs and the SM fermions as follows,

$$\text{Scalar int. (S) : } \quad \mathcal{L}_S = \sum_f \frac{G_{S,f}}{\sqrt{2}} \bar{\chi}^\mu \chi_\mu \bar{f} f, \quad (63)$$

$$\text{Pseudoscalar int. (P) : } \quad \mathcal{L}_P = \sum_f \frac{G_{P,f}}{\sqrt{2}} \bar{\chi}^\mu \gamma_5 \chi_\mu \bar{f} \gamma_5 f, \quad (64)$$

$$\text{Vector int. (V) : } \quad \mathcal{L}_V = \sum_f \frac{G_{V,f}}{\sqrt{2}} \bar{\chi}^\rho \gamma^\mu \chi_\rho \bar{f} \gamma_\mu f, \quad (65)$$

$$\text{Axialvector int. (A) : } \quad \mathcal{L}_A = \sum_f \frac{G_{A,f}}{\sqrt{2}} \bar{\chi}^\rho \gamma^\mu \gamma_5 \chi_\rho \bar{f} \gamma_\mu \gamma_5 f, \quad (66)$$

$$\text{Tensor int. 1 (T1) : } \quad \mathcal{L}_{T1} = \sum_f \frac{G_{T1,f}}{\sqrt{2}} \bar{\chi}^\mu \sigma^{\rho\sigma} \chi_\mu \bar{f} \sigma_{\rho\sigma} f, \quad (67)$$

$$\text{Tensor int. 2 (T2) : } \quad \mathcal{L}_{T2} = \sum_f \frac{G_{T2,f}}{\sqrt{2}} i(\bar{\chi}^\mu \chi^\nu - \bar{\chi}^\nu \chi^\mu) \bar{f} \sigma_{\mu\nu} f, \quad (68)$$

$$\text{Tensor int. 3 (T3) : } \quad \mathcal{L}_{T3} = \sum_f \frac{G_{T3,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} i(\bar{\chi}_\mu \chi_\nu - \bar{\chi}_\nu \chi_\mu) \bar{f} \sigma_{\rho\sigma} f, \quad (69)$$

$$\text{Tensor int. 4 (T4) : } \quad \mathcal{L}_{T4} = \sum_f \frac{G_{T4,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} \bar{\chi}^\tau \sigma_{\mu\nu} \chi_\tau \bar{f} \sigma_{\rho\sigma} f, \quad (70)$$

$$\text{Tensor int. 5 (T5) : } \quad \mathcal{L}_{T5} = \sum_f \frac{G_{T5,f}}{\sqrt{2}} (\bar{\chi}^\mu \gamma_5 \chi^\nu - \bar{\chi}^\nu \gamma_5 \chi^\mu) \bar{f} \sigma_{\mu\nu} f, \quad (71)$$

$$\text{Tensor int. 6 (T6) : } \quad \mathcal{L}_{T6} = \sum_f \frac{G_{T6,f}}{\sqrt{2}} \varepsilon^{\mu\nu\rho\sigma} (\bar{\chi}_\mu \gamma_5 \chi_\nu - \bar{\chi}_\nu \gamma_5 \chi_\mu) \bar{f} \sigma_{\rho\sigma} f, \quad (72)$$

$$\text{Scalar-Pseudoscalar int. (SP) : } \quad \mathcal{L}_{SP} = \sum_f \frac{G_{SP,f}}{\sqrt{2}} \bar{\chi}^\mu \chi_\mu \bar{f} i \gamma_5 f, \quad (73)$$

$$\text{Pseudoscalar-Scalar int. (PS) : } \quad \mathcal{L}_{PS} = \sum_f \frac{G_{PS,f}}{\sqrt{2}} \bar{\chi}^\mu i \gamma_5 \chi_\mu \bar{f} f, \quad (74)$$

$$\text{Vector-Axialvector int. (VA) : } \quad \mathcal{L}_{VA} = \sum_f \frac{G_{VA,f}}{\sqrt{2}} \bar{\chi}^\mu \gamma^\nu \chi_\mu \bar{f} \gamma_\nu \gamma_5 f, \quad (75)$$

$$\text{Axialvector-Vector int. (AV) : } \quad \mathcal{L}_{AV} = \sum_f \frac{G_{AV,f}}{\sqrt{2}} \bar{\chi}^\mu \gamma^\nu \gamma_5 \chi_\mu \bar{f} \gamma_\nu f, \quad (76)$$

where the sum of f is over all the SM fermions, and the effective coupling constants G_f are real numbers with mass dimension of -2 . Since each component of χ^μ looks like a Dirac spinor, the S, P, V, A, T1, T4, SP, PS, VA and AV interactions are analogous to the S, P, V, A, T, $\tilde{T}$, SP, PS, VA and AV interactions defined in our previous work on Dirac fermionic WIMPs [50], respectively. Even though the spin-3/2 fermionic WIMP has more degrees of freedom, it is not important in the calculation of phenomenological constraints. Thus we can expect the phenomenological constraints of spin-3/2 WIMPs are also much similar to those of Dirac fermionic WIMPs. For this reason, we just give a brief discussion on spin-3/2 WIMPs in the following.

The annihilation cross sections of WIMP-antiWIMP to SM fermion-antifermion pairs are given by

$$\sigma_{S,\text{ann}} = \frac{1}{576\pi M_\chi^4} \sum_f \left(\frac{G_{S,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \frac{(s-4m_f^2)(s-4M_\chi^2)(s^2-6M_\chi^2s+18M_\chi^4)}{s}, \quad (77)$$

$$\sigma_{P,\text{ann}} = \frac{1}{576\pi M_\chi^4} \sum_f \left(\frac{G_{P,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} s(s^2-2sM_\chi^2+10M_\chi^4), \quad (78)$$

$$\sigma_{V, \text{ann}} = \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{V,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \frac{(s+2m_f^2)(s^3-2s^2M_\chi^2-2sM_\chi^4+36M_\chi^6)}{s}, \quad (79)$$

$$\begin{aligned} \sigma_{A, \text{ann}} &= \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{A,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \\ &\times \left[s^3 - 4(m_f^2 + 2M_\chi^2)s^2 + (44m_f^2M_\chi^2 + 26M_\chi^4)s - 128m_f^2M_\chi^4 - 40M_\chi^6 + 280\frac{m_f^2M_\chi^6}{s} \right], \end{aligned} \quad (80)$$

$$\begin{aligned} \sigma_{T1, \text{ann}} &= \frac{1}{216\pi M_\chi^4} \sum_f \left(\frac{G_{T1,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \\ &\times \left[s^3 + 2(m_f^2 - M_\chi^2)s^2 + 2M_\chi^2(M_\chi^2 + 10m_f^2)s + 20M_\chi^6 - 92m_f^2M_\chi^4 + 400\frac{m_f^2M_\chi^6}{s} \right], \end{aligned} \quad (81)$$

$$\begin{aligned} \sigma_{T2, \text{ann}} &= \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{T2,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} (s-4M_\chi^2) \\ &\times \left[s^2 + 4(2m_f^2 + M_\chi^2)s - 2M_\chi^2(2m_f^2 + 5M_\chi^2) - 200\frac{m_f^2M_\chi^4}{s} \right], \end{aligned} \quad (82)$$

$$\begin{aligned} \sigma_{T3, \text{ann}} &= \frac{1}{108\pi M_\chi^4} \sum_f \left(\frac{G_{T3,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} (s-4M_\chi^2) \\ &\times \left[s^2 + 4(M_\chi^2 - m_f^2)s + 10(2m_f^2 - M_\chi^2)M_\chi^2 + 160\frac{m_f^2M_\chi^4}{s} \right], \end{aligned} \quad (83)$$

$$\begin{aligned} \sigma_{T4, \text{ann}} &= \frac{1}{54\pi M_\chi^4} \sum_f \left(\frac{G_{T4,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \\ &\times \left[s^3 + 2(m_f^2 - M_\chi^2)s^2 + 2M_\chi^2(M_\chi^2 - 14m_f^2)s + 20M_\chi^6 + 100m_f^2M_\chi^4 - 320\frac{m_f^2M_\chi^6}{s} \right], \end{aligned} \quad (84)$$

$$\begin{aligned} \sigma_{T5, \text{ann}} &= \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{T5,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \\ &\times [s^3 + 4(2m_f^2 + M_\chi^2)s^2 - 2M_\chi^2(14m_f^2 + M_\chi^2)s - 136m_f^2M_\chi^4], \end{aligned} \quad (85)$$

$$\sigma_{T6, \text{ann}} = \frac{1}{108\pi M_\chi^4} \sum_f \left(\frac{G_{T6,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \quad (86)$$

$$\times [s^3 + 4(M_\chi^2 - m_f^2)s^2 + 2M_\chi^2(22m_f^2 - M_\chi^2)s + 128m_f^2M_\chi^4], \quad (87)$$

$$\sigma_{SP, \text{ann}} = \frac{1}{576\pi M_\chi^4} \sum_f \left(\frac{G_{SP,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} (s-4M_\chi^2)(s^2 - 6M_\chi^2s + 18M_\chi^4), \quad (88)$$

$$\sigma_{PS, \text{ann}} = \frac{1}{576\pi M_\chi^4} \sum_f \left(\frac{G_{PS,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} (s-4m_f^2)(s^2 - 2M_\chi^2s + 10M_\chi^4), \quad (89)$$

$$\sigma_{VA, \text{ann}} = \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{VA,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \frac{(s-4m_f^2)(s^3 - 2M_\chi^2s^2 - 2M_\chi^4s + 36M_\chi^6)}{s}, \quad (90)$$

$$\sigma_{AV, \text{ann}} = \frac{1}{432\pi M_\chi^4} \sum_f \left(\frac{G_{AV,f}}{\sqrt{2}} \right)^2 c_f \sqrt{\frac{s-4m_f^2}{s-4M_\chi^2}} \frac{(s-4M_\chi^2)(s+2m_f^2)(s^2 - 4M_\chi^2s + 10M_\chi^4)}{s}. \quad (91)$$

Taking the thermal average, we obtain

$$\langle \sigma_{S, \text{ann}} v \rangle \simeq \frac{5}{24\pi} \sum_f \left(\frac{G_{S,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \frac{T}{M_\chi}, \quad (92)$$

$$\langle \sigma_{P, \text{ann}} v \rangle \simeq \frac{1}{4\pi} \sum_f \left(\frac{G_{P,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left[1 + \frac{8 - 5m_f^2/M_\chi^2}{4(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (93)$$

$$\langle \sigma_{V, \text{ann}} v \rangle \simeq \frac{5}{18\pi} \sum_f \left(\frac{G_{V,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left[\left(1 + \frac{1}{2} \frac{m_f^2}{M_\chi^2} \right) + \frac{3(4 - 2m_f^2/M_\chi^2 + m_f^4/M_\chi^4)}{8(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (94)$$

$$\langle \sigma_{A, \text{ann}} v \rangle \simeq \frac{1}{4\pi} \sum_f \left(\frac{G_{A,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left[\frac{m_f^2}{M_\chi^2} + \frac{40 - 116m_f^2/M_\chi^2 + 103m_f^4/M_\chi^4}{36(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (95)$$

$$\langle \sigma_{T1, \text{ann}} v \rangle \simeq \frac{5}{9\pi} \sum_f \left(\frac{G_{T1,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left[\left(1 + 2 \frac{m_f^2}{M_\chi^2} \right) + \frac{38 - 61m_f^2/M_\chi^2 + 68m_f^4/M_\chi^4}{20(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (96)$$

$$\langle \sigma_{T2, \text{ann}} v \rangle \simeq \frac{11}{18\pi} \sum_f \left(\frac{G_{T2,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \frac{T}{M_\chi}, \quad (97)$$

$$\langle \sigma_{T3, \text{ann}} v \rangle \simeq \frac{22}{9\pi} \sum_f \left(\frac{G_{T3,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left(1 + 2 \frac{m_f^2}{M_\chi^2} \right) \frac{T}{M_\chi}, \quad (98)$$

$$\langle \sigma_{T4, \text{ann}} v \rangle \simeq \frac{20}{9\pi} \sum_f \left(\frac{G_{T4,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \left[1 + \frac{38 + 61m_f^2/M_\chi^2}{20(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (99)$$

$$\langle \sigma_{T5, \text{ann}} v \rangle \simeq \frac{5}{9\pi} \sum_f \left(\frac{G_{T5,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \left[1 + \frac{3(16 + 27m_f^2/M_\chi^2)}{20(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (100)$$

$$\langle \sigma_{T6, \text{ann}} v \rangle \simeq \frac{20}{9\pi} \sum_f \left(\frac{G_{T6,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left[\left(1 + 2 \frac{m_f^2}{M_\chi^2} \right) + \frac{3(16 - 27m_f^2/M_\chi^2 + 26m_f^4/M_\chi^4)}{20(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (101)$$

$$\langle \sigma_{SP, \text{ann}} v \rangle \simeq \frac{5}{24\pi} \sum_f \left(\frac{G_{SP,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \frac{T}{M_\chi}, \quad (102)$$

$$\langle \sigma_{PS, \text{ann}} v \rangle \simeq \frac{1}{4\pi} \sum_f \left(\frac{G_{PS,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \left[1 + \frac{8 + m_f^2/M_\chi^2}{4(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (103)$$

$$\langle \sigma_{VA, \text{ann}} v \rangle \simeq \frac{5}{18\pi} \sum_f \left(\frac{G_{VA,f}}{\sqrt{2}} \right)^2 c_f \left(1 - \frac{m_f^2}{M_\chi^2} \right)^{3/2} M_\chi^2 \left[1 + \frac{3(2 + m_f^2/M_\chi^2)}{4(1 - m_f^2/M_\chi^2)} \frac{T}{M_\chi} \right], \quad (104)$$

$$\langle \sigma_{AV, \text{ann}} v \rangle \simeq \frac{5}{18\pi} \sum_f \left(\frac{G_{AV,f}}{\sqrt{2}} \right)^2 c_f \sqrt{1 - \frac{m_f^2}{M_\chi^2}} M_\chi^2 \left(1 + \frac{1}{2} \frac{m_f^2}{M_\chi^2} \right) \frac{T}{M_\chi}. \quad (105)$$

When calculating the relic density of spin-3/2 WIMPs, it is worth noting that the degree of freedom for a spin-3/2 fermionic WIMP is $g = 4$.

In the low velocity limit, the scattering cross sections of P, T3, T4, T5, T6, SP, PS, VA and AV interactions between WIMPs and nuclei vanish. In the remaining interactions, the S and V interactions are spin-independent, while the A, T1 and T2 interactions are spin-dependent. The WIMP-nucleon cross sections are given by

$$\text{Scalar int. :} \quad \sigma_{S, \chi N} = \frac{m_N^2 M_\chi^2}{\pi(M_\chi + m_N)^2} \left(\frac{G_{S,N}}{\sqrt{2}} \right)^2, \quad (106)$$

$$\text{Vector int. :} \quad \sigma_{V, \chi N} = \frac{m_N^2 M_\chi^2}{\pi(M_\chi + m_N)^2} \left(\frac{G_{V,N}}{\sqrt{2}} \right)^2, \quad (107)$$

$$\text{Axialvector int. :} \quad \sigma_{A, \chi N} = \frac{5m_N^2 M_\chi^2}{3\pi(M_\chi + m_N)^2} \left(\frac{G_{A,N}}{\sqrt{2}} \right)^2, \quad (108)$$

$$\text{Tensor int. 1 :} \quad \sigma_{T1, \chi N} = \frac{20m_N^2 M_\chi^2}{3\pi(M_\chi + m_N)^2} \left(\frac{G_{T1,N}}{\sqrt{2}} \right)^2, \quad (109)$$

$$\text{Tensor int. 2 :} \quad \sigma_{T2, \chi N} = \frac{20m_N^2 M_\chi^2}{3\pi(M_\chi + m_N)^2} \left(\frac{G_{T2,N}}{\sqrt{2}} \right)^2, \quad (110)$$

where G_N ($N = p, n$) are the induced couplings of effective WIMP-nucleon interactions, related to the couplings of WIMP-quark G_q by form factors. For S, V, A and T1 (or T2) interactions, the relations between G_N and G_q are similar to Eqs. (18), (19), (54) and (55), respectively. Since all the spin-3/2 WIMP effective models (63) – (76) have effective couplings G_f with mass dimension of -2 , their validity regions are similar to those indicated in Eqs. (23) and (25).

FIG. 20. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with scalar (S) interaction from relic density [3], direct detection experiments of CDMS II [59] and XENON100 [61], PAMELA $\bar{p}/p$ ratio [67], and validity of effective theory. The yellow region denotes the invalid parameter space of effective field theory. The left (right) frame is shown for the case of universal couplings ($G_f \propto m_f$). The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for scalar-pseudoscalar (SP) interaction are very similar to those for scalar interaction, but direct detection experiments are not sensitive to SP interaction.

FIG. 21. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with pseudoscalar (P) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for pseudoscalar-scalar (PS) interaction are very similar to those for pseudoscalar interaction.

FIG. 22. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with vector (V) interaction from relic density, direct detection experiments of CDMS II and XENON100, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for vector-axialvector (VA) interaction are very similar to those for vector interaction, but direct detection experiments are not sensitive to VA interaction.

FIG. 23. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with axialvector (A) interaction from relic density, direct detection experiments of CDMS [60] and XENON10 [62], PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 24. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with tensor interaction 1 (T1) from relic density, direct detection experiments of CDMS and XENON10, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for tensor interaction 5 (T5) are very similar to those for T1 interaction, but direct detection experiments are not sensitive to T5 interaction.

FIG. 25. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with tensor interaction 2 (T2) from relic density, direct detection experiments of CDMS and XENON10, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 26. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with tensor interaction 3 (T3) from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

FIG. 27. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with tensor interaction 4 (T4) from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory. The constraints from relic density, $\bar{p}/p$ ratio and validity of effective theory for tensor interaction 6 (T6) are very similar to those for T4 interaction.

The combined constraints on coupling constants G_f of the spin-3/2 WIMP effective models of S, P, V, A, T1, T2, T3, T4 and AV interactions from relic density [3], direct detection experiments of CDMS [59, 60] and XENON [61, 62], and PAMELA $\bar{p}/p$ ratio [67] are shown in Figs. 20 – 28, with the yellow regions denoting the invalid parameter spaces

FIG. 28. Combined constraints on coupling constants G_f of spin-3/2 WIMPs with axialvector-vector (AV) interaction from relic density, PAMELA $\bar{p}/p$ ratio, and validity of effective theory.

of effective field theory. The constraints on SP, PS, T5, T6 and VA interactions are very similar to those on S, P, T1, T4 and V interactions respectively, except that the SP, T5 and VA interactions are not constrained by direct detection experiments. As stated above, the constraints on S, P, V, A, T1, T4, SP, PS, VA and AV interactions are much similar to those on the analogous interactions of Dirac fermionic WIMPs in our previous work [50], respectively. In this work, however, we adopt the latest constraint of XENON100 SI direct detection [61], which is stronger than that adopted in our previous work [50]. Thus the constraints on S and V interactions of spin-3/2 WIMPs are more stringent than those for Dirac fermionic WIMPs we calculated before. On the other hand, the T2, T3, T5 and T6 interactions have no analogue of Dirac fermionic WIMPs. From Figs. 25 and 26, we can see that the direct detection constraints on T2 and T3 interactions are so loose that only a little region of M_χ is excluded by SD direct detection in the case of T2 interaction with universal couplings. In addition, the constraints by PAMELA $\bar{p}/p$ ratio exclude the mass regions of $M_\chi \lesssim 70$ GeV for T5 and T6 interactions, while it is not sensitive to T2 and T3 interactions because their annihilation rates (97) and (98) are both of order T/M_χ . As a summary of the study on the spin-3/2 WIMP, in Table III, the excluded regions of M_χ given by direct and indirect detection experiments for spin-3/2 fermionic WIMPs with various effective interactions are shown.

V. CONCLUSIONS

In this work, we give a general analysis of the 4-particle interaction between SM particles and DM which consists of scalar, vector or spin-3/2 WIMPs. The most general forms of the 4-particle operators up to dimension 6 have been considered. We find that for scalar, vector and spin-3/2 DM, the constraints from DM relic density, DM direct and indirect detection are complementary to each other. Thus the comparison among different kinds of experimental results gives us a complete picture about the current DM searches. In general, the constraints from SI direct detection are the most stringent, while those from SD direct detection are quite weak. On the other hand, for light DM (whose mass $\lesssim 70$ GeV) the cosmic-ray $\bar{p}/p$ data can be more sensitive than direct detection or relic density in some cases.

Assuming one operator dominates the effective interaction between DM and SM fermions, we find that in some cases the constraints are so strong that the Universe will be overclosed by DM thermal production. If the standard cosmology is still retained, the DM models in such cases should be excluded, which are indicated in Tables I, II and III. In the case of scalar DM, recent direct detection experiments exclude some M_ϕ regions for S and V interactions, while the PAMELA $\bar{p}/p$ ratio excludes some small M_ϕ regions ($\lesssim 70$ GeV) for S and SP interactions. In the case of vector DM, recent direct detection experiments exclude some M_X regions for S and V interactions, and for $\tilde{V}A$ interaction only with universal couplings. The PAMELA $\bar{p}/p$ ratio, however, excludes some small M_X regions ($\lesssim 70$ GeV) for S, T, SP and $\tilde{T}$ interactions, and most of these interactions cannot be excluded by direct detection. In the case of spin-3/2 DM, the constraints on most interactions (S, P, V, A, T1, T4, SP, PS, VA and AV) are much similar to those on their analogous interactions of Dirac fermionic DM in our previous work [50]. Besides, the constraints on T2 and T3 interactions are so weak that only direct detection can exclude a little region of M_χ in the case of T2 interaction with universal couplings. For T5 and T6 interactions, some small M_χ regions ($\lesssim 70$ GeV) are excluded by the PAMELA $\bar{p}/p$ ratio. Among the scalar, vector and spin-3/2 DM effective models, there are still some effective interactions to which the recent DM direct and indirect search experiments are not sensitive at all.

TABLE III. A summary for spin-3/2 WIMPs with various effective interactions. The excluded regions of M_χ given by direct and indirect experiments are indicated.

Universal couplings		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_\chi \simeq 10$ GeV – above 1 TeV	Not sensitive
P	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
V	Excluded $M_\chi \simeq 10$ GeV – above 1 TeV	Excluded $M_\chi \simeq 10 - 70$ GeV
A	Not sensitive	Excluded $M_\chi \simeq 10 - 17$ GeV
T1	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T2	Excluded $M_\chi \simeq 15 - 24$ GeV	Not sensitive
T3	Not sensitive	Not sensitive
T4	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T5	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T6	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
SP	Not sensitive	Not sensitive
PS	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
VA	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
AV	Not sensitive	Not sensitive

$G_f \propto m_f$		
Interaction	Direct detection	PAMELA $\bar{p}/p$
S	Excluded $M_\chi \simeq 10 - 240$ GeV	Not sensitive
P	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
V	Excluded $M_\chi \simeq 25 - 29$ GeV	Excluded $M_\chi \simeq 10 - 70$ GeV
A	Not sensitive	Excluded $M_\chi \simeq 10 - 30$ GeV
T1	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T2	Not sensitive	Not sensitive
T3	Not sensitive	Not sensitive
T4	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T5	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
T6	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
SP	Not sensitive	Not sensitive
PS	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
VA	Not sensitive	Excluded $M_\chi \simeq 10 - 70$ GeV
AV	Not sensitive	Not sensitive
